

# Foundations of C Programming (Structured Programming)

## - Array

# Outline

- The concept of array
- One-dimension array (一维数组)
- Multi-dimension array (多维数组)

# Array

If we are required to write a program to calculate the average of 50 grades for a class of students, how can we write that program?

```
int grade1, grade2, grade3, ..., grade50;
```

50 variables!

# Array

- An array (数组) offers a solution to this problem
- Array is a derived data type
  - It itself is not a type
  - Every element in the array has **same type**
  - E.g., instead of the declaration like

```
int grade1, grade2, grade3, ..., grade50;
```

- We can declare

```
int grade[50];
```

# Array

- If we declare

```
int grade[50];
```

- We can refer to each element in the array with **index**. E.g.

```
int grade[50];  
  
grade[0] = 10;  
grade[1] = 10;
```

```
int grade[50];  
int i;  
  
for (i = 0; i < 50; i++)  
    grade[i] = 100;
```

- Attention
  - The **first** element in an array has the index **0**
  - The **last** element in an array has the index **49** (in this example), i.e., grade[50] is not allowed.

# Bounds of An Array

- The **size** of an array is the total number of elements in the array
- Remember that the array index is from **0** to **size – 1**.
- Writing over the bounds of an array is a **common** source of error. It might change the values of other variables.

# Initializing An Array

- Three ways to initialize an array

```
int grade[4];  
  
grade[0] = 10;  
grade[1] = 20;  
grade[2] = 30;  
grade[3] = 40;
```

```
int grade[4] = {10, 20, 30, 40 };
```

```
int grade[] = {10, 20, 30, 40 };
```

# An Example

```
int main() {  
    int a[5];  
    int i;  
  
    for (i = 0; i < 5; i++)  
        a[i] = i;  
  
    for (i = 0; i < 5; i++)  
        printf("a[%d] = %d\n", i, a[i]);  
    return 0;  
}
```

1. What is the output of this program?
2. Can we change  $i < 5$  to  $i \leq 5$ ?

# An Example

```
int main() {  
    int grade[5]= {1, 2, 3, 4, 5};  
    int i, sum;  
    float average;  
  
    for (i = 0; i <= 5; i++)  
        sum = sum + grade[i];  
    average = (float)sum / i;  
    return 0;  
}
```

1. What is this program supposed to do?
2. Are there any problems in this program?

# Array Size

```
int a[5];
```

✓

```
int n = 5;  
int a[n];
```

✓

```
int n;  
scanf("%d", &n);  
int a[n];
```

✓

```
int n;  
int a[n];  
scanf("%d", &n);
```

✗

# Multi-Dimensional Arrays

- Arrays in C programs can have virtually as many dimensions as you want.
- Declaration is accomplished by adding additional subscripts when it is defined.
- E.g. `int table[4][3];`
  - defines a **two-dimensional** array (二维数组)

# Multi-Dimensional Arrays

- E.g. `int table[4][3];`
  - We can understand this as
    - `table` is an array of `table[0]`, `table[1]`, `table[2]`, and `table[3]`

<code>table[0]</code>	<code>table[0][0]</code>	<code>table[0][1]</code>	<code>table[0][2]</code>
<code>table[1]</code>	<code>table[1][0]</code>	<code>table[1][1]</code>	<code>table[1][2]</code>
<code>table[2]</code>	<code>table[2][0]</code>	<code>table[2][1]</code>	<code>table[2][2]</code>
<code>table[3]</code>	<code>table[3][0]</code>	<code>table[3][1]</code>	<code>table[3][2]</code>

# Initializing An Array

- Three ways to initialize(初始化) a multi-dimensional array (多维数组)

```
int grade[2][3];  
  
grade[0][0] = 10;  
grade[0][1] = 20;  
grade[0][2] = 30;  
grade[1][0] = 40;  
grade[1][1] = 50;  
grade[1][2] = 60;
```

```
int grade[2][3] = {10, 20, 30, 40, 50, 60};
```

```
int grade[2][3] = {{10, 20, 30}, {40, 50, 60}};
```

# An Example

```
int main (){
    int random[2][2];
    int i, j;

    for (i = 0; i < 2; i++){
        for (j = 0; j < 2; j++){
            random[i][j] = (i+j)%2;
            printf ("%c " , random[i][j] ? 'x' : 'o');
        }
        printf("\n");
    }
    return 0;
}
```

# String

- A string (字符串) is an **array of chars**
  - E.g., `char s[10];`
    - `s` is a string which can store at most 10 characters
- A string must end at `'\0'`.

# An Example to String Initialization

```
int main () {  
    char word[20];  
  
    word[0] = 'H';  
    word[1] = 'e';  
    word[2] = 'l';  
    word[3] = 'l';  
    word[4] = 'o';  
    word[5] = '\\0';  
  
    printf("The word is %s\\n", word );  
    // %s: output a string ending at '\\0'  
    return 0;  
}
```

# Another Way to Initialize String

```
int main () {  
    char word[20] = "Hello"; ✓  
  
    printf("The word is %s\n", word );  
    return 0;  
}
```

```
int main () {  
    char word[20];  
  
    word = "Hello"; //illegal assignment ✗  
    printf("The word is %s\n", word );  
    return 0;  
}
```

Attention: '\0' had been automatically added to the end of string in the first example.

# Class Exercise

```
int main () {  
    char word[20]= "Hello";  
  
    printf("The second char is %c" \n", word[1]);  
    return 0;  
}
```

Output?

# Class Exercises

- What is the value of `a[2]` if we have the following initialization of an array
  - `int a[5] = {2, 4, 6, 8, 10}`
- What is the value of `a[2][1]` if we have the following initialization of an array
  - `int a[2][3] = {2, 4, 6, 8, 10, 12}`

# An Example: Sorting Data in An Array

- Sometimes we need to sort an array in descending order (降序) or ascending order(升序)
- For example
  - An array: 10 30 20 40
  - Descending order: 40 30 20 10
  - Ascending order: 10 20 30 40
- Program in the next page
  - implements decedent ordering
- More interesting algorithms can be used in sorting
  - Explore after the class

```
#include <stdio.h>
```

```
int main(){  
    int n, i, j;
```

```
    printf("Input the total number of integers: \n");  
    scanf("%d", &n);  
    int a[n];
```

```
    printf("Please input the integers to sort: \n");  
    for (i = 0; i <= n-1; i++)  
        scanf("%d", &a[i]);
```

```
    for (i = 0; i <= n-2; i++)  
        for (j = i+1; j <= n-1; j++){  
            if (a[i]<a[j]){  
                int temp;  
                temp = a[j];  
                a[j] = a[i];  
                a[i] = temp;  
            }  
        }  
}
```

```
    printf("Sorted integers in descendent order\n");  
    for (i = 0; i <= n - 1; i++)  
        printf(" %d ", a[i]);  
    return 0;
```

```
}
```

```
n = 4;
```

a[0]	a[1]	a[2]	a[3]
10	30	20	40

```
-----  
i = 0
```

```
j: 1 ~ 3
```

```
j=1: 30 10 20 40
```

```
j=2: 30 10 20 40
```

```
j=3: 40 10 20 30
```

```
-----  
i = 1
```

```
j: 2 ~ 3
```

```
j=2: 40 20 10 30
```

```
j=3: 40 30 10 20
```

```
-----  
i = 2
```

```
j: 3 ~ 3
```

```
j=3: 40 30 20 10
```

Descending

# Summary

- Array can be used to store a set of data with same data type.
- Index of an array should not exceed the upper limit.
- Array can be used to store a string.
